

1. Project 5 — Language Translation — 10/10

This project creates a system that takes text in one language and translates it into another language. It is similar to the basic idea behind tools like Google Translate, where the computer has to understand a sequence of words and generate a new sequence that keeps the same meaning. I think this would be very interesting because language-based AI is becoming more important and it would be different from the types of machine learning projects I have worked on before. sem01

2. Project 4 — Stock Market Trend Prediction — 10/10

This project looks at past stock market data and tries to predict what may happen next. The important idea is learning from data that changes over time and using past patterns to estimate future behavior. I find this very interesting because the same type of idea could be applied to many other kinds of time-based data, such as sensor readings, medical data, or manufacturing data. sem01

3. Project 8 — Face Detection — 9/10

This project creates a system that can find human faces in pictures or video. It can also identify parts of the face, such as the eyes and smile. I think this would be interesting because you can actually see the computer reacting to visual information, and it could eventually connect to applications involving cameras, robotics, or other intelligent systems. sem01

4. Project 10 — Customer Segmentation — 8/10

This project looks at customers' income and spending behavior and separates them into groups of people with similar habits. A company could use those groups to better understand its customers and decide who to market certain products toward. I like this project because it combines data analysis with a real business application. sem01

5. Project 7 — Movie Recommendation System — 8/10

This project creates a system that recommends movies based on relationships between movies a person already likes. It is similar to the basic idea behind recommendation systems used by streaming services. I think this would be interesting because recommendation systems are used in many real applications and can be expanded beyond movies. sem01

6. Project 9 — Handwritten English Character Recognition — 7/10

This project creates a system that looks at an image of a handwritten English letter and determines which letter it is. Unlike a project where there are only two possible answers, this system has to choose between many different letters. I think it would be interesting because it shows how computers can understand handwritten information, although I have already had some experience with image classification. sem01

7. Project 3 — Used Car Sale Price Prediction — 7/10

This project uses information about used cars to estimate how much a car should sell for. The computer learns from examples of previous cars and their prices and then uses those patterns to make new predictions. I think it could be useful and practical, although the application itself is not as interesting to me as some of the other projects. sem01

8. Project 6 — Cats and Dogs Image Classification — 6/10

This project teaches a computer to look at an image and determine whether it contains a cat or a dog. The larger idea is teaching a computer to recognize and classify objects in images. I like computer vision, but this project interests me less because I have already worked on image-classification projects and would rather learn something new. sem01

9. Project 2 — Spam Email Detection — 6/10

This project creates a system that reads a message and decides whether it is spam or a normal message. It learns from messages that have already been labeled and then uses those examples to classify new messages. I think text classification is useful, but I would rather work on the more advanced language translation project if I am working with text. sem01

10. Project 1 — House Price Prediction — 5/10

This project uses information about houses to estimate how much a house should sell for. It learns relationships between housing information and previous sale prices and then uses those relationships to predict new prices. I think it is a useful introduction to machine learning, but it is less interesting to me because I would rather work on something involving language, time-based data, or more advanced AI applications.
